ACES CENTRAL

ACES 1.1 now available

ACES Info

Alex Forsythe

Welcome to the ACES Community

Today we have a new series of new features incremented to 1.1, the look or modification of the ACES version 1.1. A series of new features were added at this point on a P3 display colorimetry to be also added for R, with limiting to P3 P3D60. These are ACES releases.

ACES 1.1 also includes an ODT into ODTs. The new Color individual Output Transform improve the consistency that are specified display max luminance primaries (if any) Output Transform devices in dark in both dark and motion pictures in the surround part EOTF is set to all

ACES

The Academy Color Encoding System — Overview

These days, a film or TV show is unlikely to use only one type of camera for every setup, and indeed different camera types may be used to cover different angles within the same setup. Between filming and final deliverables, the content will pass through a range of software applications, and be handled by a number of creative and technical teams, often in different locations. And it is likely that the deliverables will take multiple forms, each intended for viewing on a particular type of display in a particular environment. Now more than ever, it's vital to implement image processing pipelines that ensure color consistency at every stage.

The **Academy Color Encoding System** is designed to do exactly this. It defines a common working color space into which content from different sources can be transformed, and Output Transforms for all the common display standards, so that the captured images will be perceptually consistent no matter where or at what stage they are viewed. While big facilities with in-house color specialists may have their own custom workflows, an ACES-based pipeline simplifies the implementation of robust color management from filming, through editorial, VFX and DI, all the way to distribution. ACES includes clearly defined standards and best practices, that are implemented in a wide range of software tools, and can be added to many others through the use of plugins.

ACES Color Science

Modern digital cinema cameras — even many lower-end models — are able to record in raw or log modes to capture **scene-referred** images. This means that the captured images have a known (and invertible) mathematical relationship to the light in the photographed scene, as opposed to **display-referred** images, which are designed simply to “look good” on a particular monitor. The output of a sensor is always scene-referred, but traditional video cameras add a display transform to the image, converting it to display-referred before recording. ACES delays the application of the display transform (Output Transform or ODT in ACES terminology) to the end of the production pipeline, which allows not only greater image fidelity, but also more flexibility when it comes to VFX and color grading. Additionally, a variety of Output Transforms can be applied to an individual scene-referred image in order to target different displays, such as Rec. 709, ST 2084 (HDR) or DCI (cinema).

The scene-referred recordings from different cameras use different custom encodings that have been optimized for the capabilities of the particular camera. Log curves fit the dynamic range of the camera into a limited bit depth for recording, and color primaries are chosen to minimize wasted code values. These differences mean that unique display transforms are needed to map each camera's content to a given display. ACES circumvents this issue by defining a color space, ACES2065-1, that encompasses the entire range of visible colors, and an encoding that uses 16-bit floating point values. As a result, captured images from any camera can be transformed to the space using simple mathematical operations called Input Transforms (ITs). From ACES, the same Output Transforms can be used to render the images for different displays, regardless of the camera source. The same is possible for computer-generated imagery (CGI), meaning that all images can be handled in the same way.

ACES Project Checklist

Visual Effects Supervisors / Artists

This checklist is intended to help you organize your first couple of ACES projects, after which this should be second nature for you. Many of these steps identify any ACES-specific questions you need to ask answers.

Getting Started

- As ever, communication is key. While ACES simplifies settings, there are still some decisions to be made viewing the image at various stages, and thorough be assured. This is the primary issue that ACES at every step, and for every collaborator.

File Formats

- Discuss who is doing the VFX pulls, and the format ACES2065-1 encoding or in the native color space the traditional 10-bit version should be avoided, as captured by modern digital cameras.
- The ACES standard for interchange is 16-bit uncolor with the **ACES Image Container** flag set (defined uncommon for facilities to use ACEScsg for internal should be taken to ensure that ACEScsg files are not ACES Image Container flag should never be set for any external interchange.

Working with DI

- Test a round-trip back to DI and editorial, to ensure unaffected by the process, and exactly match those for editorial. Make sure that any plate normalization be removed in final renders. Simple ASC CDL type communicating on-set looks to VFX and DI.
- Communicate with the colorist / DIT / dailies colorist ensure you apply them in the intended color space linear ACES2065-1 for CLF (Common LUT Format Look Modification Transforms or LMTs). The same look identical in the mid-tones and highlights, so it immediately noticed, but the shadow handling will so that work-in-progress renders drop seamlessly
- Decide whether you are using LUTs which have the Device Transform or ODT baked in or grade only eliminates the ability to switch Output Transforms LUTs will also eliminate the option to toggle the grade

Compositing

- Make sure you have access to all custom Input Transforms (sometimes called Input Device Transforms or IDTs) for cameras used on the show, and make sure you have them in a form that can be used in your compositing software.
- If you are using software such as Nuke, a move to ACES will not have a significant impact on the way you work. Nuke was designed from the ground up to work with linear image data – the same as ACES. However Nuke's legacy color management does not specify a working color space, and it simply linearizes the image data with its current primaries, and uses 1D display transforms with no tone-mapping for values above 1.0. Recent versions use Open Color IO (OCIO) for color management. OCIO has options to mimic Nuke's legacy approach, but also includes a pre-built [configuration for ACES](#).
- Software such as After Effects is geared towards working in a display-referred way, where the actual pixel values sent to the screen are manipulated. Display device color management is provided via ICC profiles which compensate for the difference between a standard and the actual display in use, although many people disable this feature. Moving to ACES will therefore involve a slight change of mindset, working on scene-referred image data, and viewing the result through an ACES Output Transform. This can be implemented in After Effects using the [ACES OCIO plugin](#) from FxSoftware. Besides the standardization of input and output transforms that ACES brings, there are many other noticeable benefits to moving to scene linear, such as more realistic focus and exposure changes, without the need for 'cheats'.

CGI

- Some 3D software (e.g. Cinema 4D) works internally in a high dynamic range linear way, but the software's viewport treats this image data as display linear, offering only simple 1D view transforms that clip values greater than 1.0. The software may provide a highlight compression slider, but it is likely to use an unspecified algorithm that does not match the tone mapping of ACES. This means that rendering to an EXR (which generally requires a *linear sRGB* IDT in comp or DI) will result in an ACES image that does not match what was seen in the viewport. This difference must be accounted for when lighting and texturing, and the tendency to alter the scene to make it 'look right' through the viewport's simple sRGB view transform should be avoided. The need to use LUTs or ICC profiles to preview the ACES look is discussed in [this thread](#) on ACES Central.

Simple sRGB Viewer LUT

ACES sRGB Output Transform

- HDR1 environment captures should easily drop into an ACES pipeline, as they are already high dynamic range scene referred data. The only consideration is whether the primaries need to be mapped to ACEScsg (AP1) primaries, to match the rendering color space. Texture libraries or your own SDR texture captures will also need to be converted to ACEScsg. In this case a simple inverse sRGB transform plus a matrix should be sufficient, as textures should not contain image data above diffuse white.

081318-1

ACES 1.0 Listening Tour Feedback

- 42 interviews with individuals or groups
 - Color/Image Scientists
 - Colorist
 - Content Owners
 - DITs
 - DPs
 - Manufacturers (Cameras, Software)
 - VFX Companies + RAE Paper
 - Other general users
 - Prior ACES Leadership
- Over 80 individuals (not including RAE authors and contributors)
- Nearly 450 comments to parse through
- 48 main points of feedback

ACES 1.0 Listening Tour Results

Top Ten (starting with the one with the most votes)

1. RRT needs to be invertible and separate the “look” from the RRT (put look in LMT)
2. ACESclip needs to be defined and implemented in tools
3. Need a way to exchange and archive LMTs; re-look at CLF and implement in all tools
4. Need to fix negative values issue (not just through an LMT)
5. CTL is good for prototyping and to define the intention, but because it’s not realtime, it isn’t viable in production; need to look other implementations
6. Allow for custom IDTs, including camera color gamut matching
7. Should be able to customize ODTs (including parametric) and publish them
8. Allow for color grading in non-ACES spaces (like the Original Camera Color Gamut and tonal curve). Must be able to document for archive
9. Should take a look at the AP0/AP1 gamuts including why AP1 red is outside of AP0, why AP1 does not equal 2020 and other issues
10. Remove modifiers from ODTs; make ODTs more like standard 709 and P3

ACESNext Process Going Forward

- Governance
 - Work towards Open Source model

The AMPAS Esmeralda Room

IDT VWG

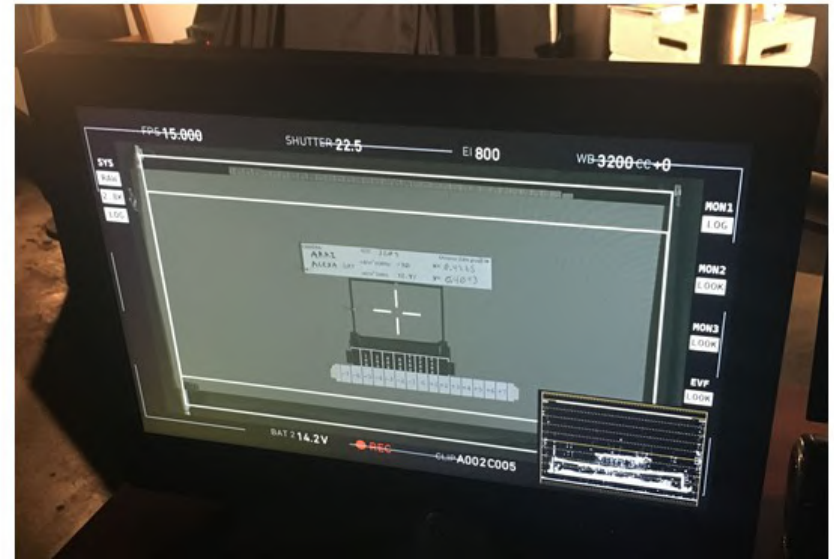

Steve Yedlin, ASC

Joshua Pines, Technicolor

Joachim Zell, EFILM

Academy "Esmeralda Room"

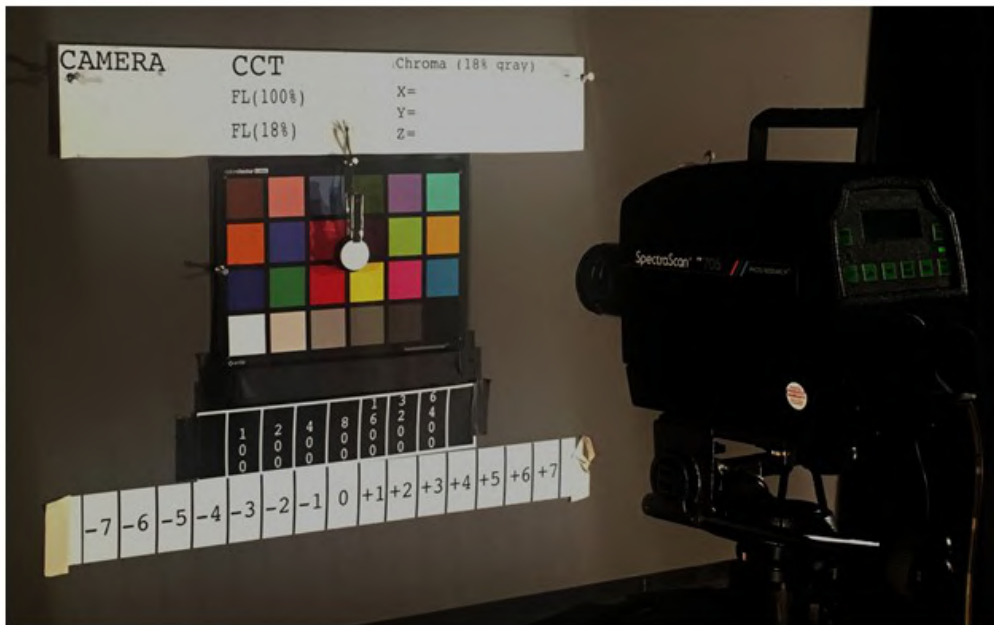

- chart square on
- chart is in the center of the frame
- camera's distance, chart one quarter of a 35mm frame

the luminaires on either side of the camera are located 45 degrees off of the lens axis

The room status gets verified by a Photo Research Spectroradiometer
An exposure meter is used to set the cameras ISO, shutter angle, and frame-rate settings

For the Esmeralda Room recordings,
we decided to go for distance of 12' between gray card and focal point of the camera

When setting the stop, start with the iris wide open and close down to the marked t/stop
don't start closed and open to your stop
(because lenses are marked to account for backlash in the mechanism).

To calculate the “over and under stops” @ 800 ISO,

We used the following formula:

$$\text{stop} = \text{Log}_2 \left(\left(L * (S/N^2) * (1/F) * (A/360) \right) / K \right)$$

Where:

N is the f-number of the lens setting (in our case f5.6)

L is the average scene luminance in cd/m²

(in this case the gray card luminance = 30 cd/m²)

S is the ISO (in our case 800 ISO)

K is the calibration constant (which we’re saying is 12.5 — that’s what Sekonic and others use and seems to coincide with reality of how real-world exposures predict photographic results)

F is Frame Rate in FPS

A is the Shutter Angle

The Academy Digital Source Master A Future-Proof Deliverable

Dr. Wolfgang Ruppel
RheinMain University of Applied Sciences

Agenda

- What problem are we going to solve?
- IMF Application #5 ACES
- The Academy Digital Source *Master Specification*
- Status of implementation
- Conclusion

What problem are we going to solve?

For a given product you've got:

- Final ACES master files (textless) - ST 2065-4 (OpenEXR)
- Final ACES master files (localized) - ST 2065-4 (OpenEXR)
- Related metadata - ODT, RRT, LMT
- Audio soundfields - WAV, Immersive soundfields
- Data essence - Timed Text...

...and you want to deliver and archive all of that in one consistent package?

The Academy Digital Source Master specification, built on IMF App#5, does the job!

Outline of IMF App #5 ACES

- IMF Application #5 ACES is published as SMPTE ST 2067-50
 - Specifies SMPTE ST 2065-5 MXF wrapping for Image Track Files
 - Any frame rate and any spatial resolution is supported
 - Defines metadata structures

Metadata in IMF App #5 ACES

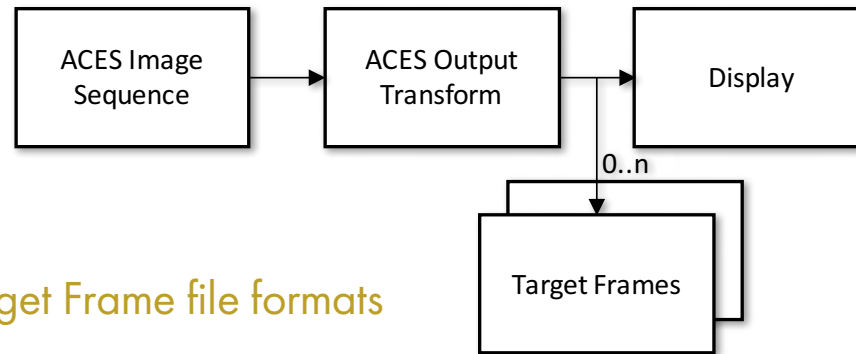

- ACES files are presented by means of an Output Transform

- **The challenge: How to document the Output Transform used in Mastering for delivery and archiving?**
- **The solution in IMF Application #5:**
 1. ACES Authoring Information metadata
 2. Mastering Display metadata
 3. "Target Frames" – Essence frames rendered in a display-referred color space

Metadata in App #5: Target Frames

- Target Frames are provided to calibrate the IMF package “playback” display system and environment to match the original mastering display system and environment

- PNG and TIFF supported as Target Frame file formats
- If the Target Frames visually or mathematically match the rendered images obtained from a particular workflow, it ensures that the particular playback display system and environment recreates the artistic intent applied during the mastering process of the original ACES Image sequence

Constraining and enhancing IMF App #5

- A normative requirement to provide Output Transform metadata
- A specification for Look Modification Transform metadata

Introducing...

The Academy Digital Source Master Specification

Specification

S-2018-001

**Academy Color Encoding System -
The Academy Digital Source Master**

The Academy of Motion Picture Arts and Sciences
Science and Technology Council
Academy Color Encoding System (ACES) Project Committee

August 24, 2018

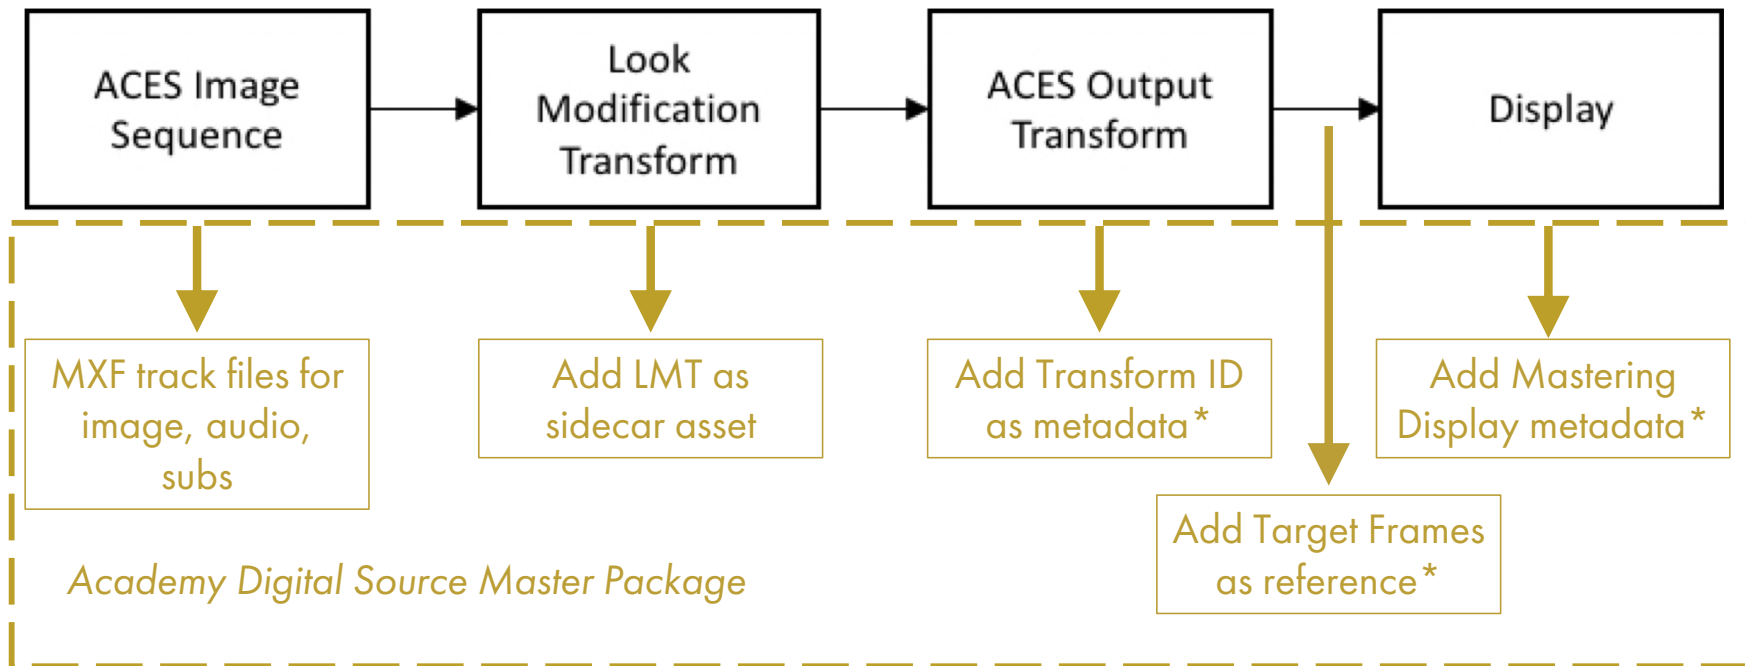

Summary: This document specifies an application for the exchange and archiving of final ACES 1.0 master files along with an arbitrary number of soundfield group tracks and timed text tracks

The Academy Digital Source Master specification

- Based on IMF Application #5 ACES (SMPTE ST 2067-50)
- Requirement to specify one (or more) Academy-provided Output Transform IDs as metadata
 - Example: `ODT.Academy.Rec2020_1000nits_15nits_ST2084.a1.1`
- Option to provide one (Global) Look Modification Transform in addition to an Output Transform
 - Technically, LMTs will be added to the IMF package as “sidecar assets”

The Academy Digital Source Master specification

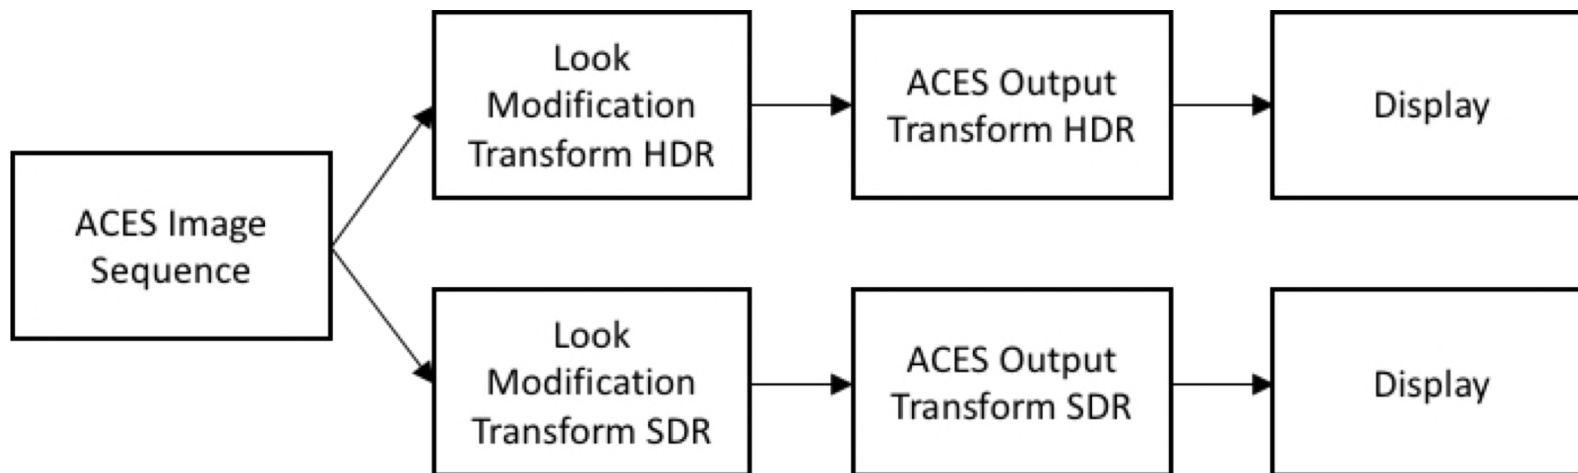

Enhanced workflow using Look Modification Transform (LMT)

*contained in ACES Image Track Files

The Academy Digital Source Master specification

Future-proof, prepared for multiple device ACES master file sets (“Über-Master”)

Interoperability and implementations

- IMF vendors have demonstrated interoperability at the recent SMPTE IMF Plugfest in October 2018
- The SMPTE IMF Plugfest was hosted by the Academy
 - 10+ vendors participating
 - IMF App#5 was one of the test vectors
 - All IMF App#5 packages provided were compliant and fully interoperable

Open Source software: IMF Tool

The screenshot displays the IMF Tool interface, which is divided into several functional areas:

- IMP Browser (Left Panel):** Lists assets with columns for Icon, rel. File Path, File Size, Finalized, and Annotation. Assets include WAV_27b7..., aces_target..., aces_nc..., CPL_4b..., CPL_a9582..., and CPL_720e9... Callouts include "Add New Track" and "The IMP Browser shows all assets of an IMP. Double-click CPL to edit the timeline."
- Details Panel (Top Center):** Shows metadata for the selected asset, including Content Title (NGCT), Issuer (RheinMain University), Content Originator (AMPAS), Content Kind (test), Annotation (NGCT), Edit Rate (24), Issue Date (22.01.19 20:57), and Application (http://www.smpte-ra.org/ns/2067-50/2017). Callouts include "Edit CPL metadata" and "Set Edit".
- Image Preview (Top Right):** Displays a video frame with a woman in a uniform. Callout: "Image Preview".
- Timeline (Bottom):** Shows a timecode (00:00:00:00) and a track layout with Video and Audio tracks. Callout: "Drag&Drop assets into the timeline".

Track	Asset Name	In	Out	Duration
Video	aces_target_frames_01.mxf	00:00:00:00	00:00:00:23	24
Audio	WAV_27b776f6-5cca-40c3-9902-a15c71e79953.mxf	00:00:00:00	00:00:00:23	24

Conclusion

- Academy Digital Source Master is the solution for delivery and archiving of ACES master file sets
- The Academy Digital Source Master specification defines a future-proof data structure
- Based on Industry Requirements of all Major Hollywood studios
- Vendors have demonstrated implementations & interoperability at a plug-fest in October 2018
- Open Source software (IMF Tool and C++ libraries) enables sustainable archiving and broad access
